Relational Algebra & SQL

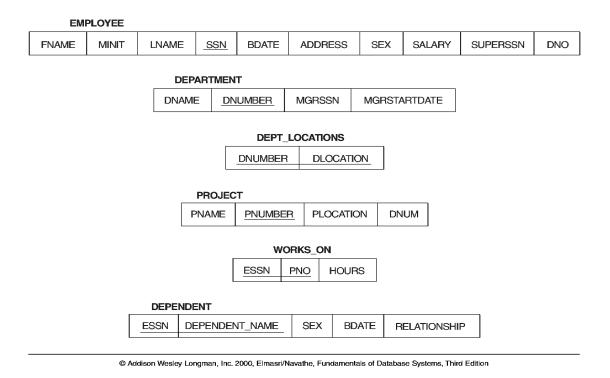

Module 3.1

- Relational Algebra
- Relational Algebra Queries

Database State for COMPANY

All examples discussed below refer to the COMPANY database shown here.

Figure 7.5 Schema diagram for the COMPANY relational database schema; the primary keys are underlined.

Relational Algebra

- The basic set of operations for the relational model is known as the relational algebra. These operations enable a user to specify basic retrieval requests.
- The result of a retrieval is a new relation, which may have been formed from one or more relations. The **algebra operations** thus produce new relations, which can be further manipulated using operations of the same algebra.
- A sequence of relational algebra operations forms a **relational algebra expression**, whose result will also be a relation that represents the result of a database query (or retrieval request).

Unary Relational Operations

• **SELECT Operation**

SELECT operation is used to select a *subset* of the tuples from a relation that satisfy a **selection condition**. It is a filter that keeps only those tuples that satisfy a qualifying condition – those satisfying the condition are selected while others are discarded.

Example: To select the EMPLOYEE tuples whose department number is four or those whose salary is greater than \$30,000 the following notation is used:

 $\sigma_{DNO} = 4 (EMPLOYEE)$

OSALARY > 30,000 (EMPLOYEE)

In general, the select operation is denoted by σ < selection condition > (R) where the

symbol σ (sigma) is used to denote the select operator, and the selection condition is a Boolean expression specified on the attributes of relation R

Unary Relational Operations

SELECT Operation Properties

- The SELECT operation $\sigma_{\text{selection condition}}(R)$ produces a relation S that has the same schema as R
- The SELECT operation σ is **commutative**; i.e.,

$$\sigma < condition 1 > (\sigma < condition 2 > (R)) = \sigma < condition 2 > (\sigma < condition 1 > (R))$$

• A cascaded SELECT operation may be applied in any order; i.e.,

```
\begin{aligned} & \sigma_{\text{<condition1>}}(\sigma_{\text{<condition2>}}(\sigma_{\text{<condition3>}}(R)) \\ &= \sigma_{\text{<condition2>}}(\sigma_{\text{<condition3>}}(\sigma_{\text{<condition1>}}(R))) \end{aligned}
```

• A cascaded SELECT operation may be replaced by a single selection with a conjunction of all the conditions; i.e.,

```
\sigma < condition 1 > (\sigma < condition 2 > (\sigma < condition 3 > (R))
= \sigma < condition 1 > AND < condition 2 > AND < condition 3 > (R))
```

Figure 7.8 Results of SELECT and PROJECT operations.

PROJECT Operation

This operation selects certain *columns* from the table and discards the other columns. The PROJECT creates a vertical partitioning – one with the needed columns (attributes) containing results of the operation and other containing the discarded Columns.

Example: To list each employee's first and last name and salary, the following is used:

 $\pi_{\text{LNAME, FNAME,SALARY}}(\text{EMPLOYEE})$

The general form of the project operation is π <attribute list>(R) where π (pi) is the symbol used to represent the project operation and <attribute list> is the desired list of attributes from the attributes of relation R.

The project operation *removes any duplicate tuples*, so the result of the project operation is a set of tuples and hence a valid relation.

PROJECT Operation Properties

- The number of tuples in the result of projection $\pi_{\langle list \rangle}(R)$ is always less or equal to the number of tuples in R.
- If the list of attributes includes a key of R, then the number of tuples is equal to the number of tuples in R.
- . $\pi_{< list1>}(\pi_{< list2>}(R)) = \pi_{< list1>}(R)$ as long as < list2> contains the attributes in < list2>

Rename Operation

We may want to apply several relational algebra operations one after the other. Either we can write the operations as a single **relational algebra expression** by nesting the operations, or we can apply one operation at a time and create **intermediate result relations**. In the latter case, we must give names to the relations that hold the intermediate results.

Example: To retrieve the first name, last name, and salary of all employees who work in department number 5, we must apply a select and a project operation. We can write a single relational algebra expression as follows:

$$\pi_{\text{FNAME, LNAME, SALARY}}(\sigma_{\text{DNO}=5}(\text{EMPLOYEE}))$$

OR We can explicitly show the sequence of operations, giving a name to each intermediate relation:

DEP5_EMPS
$$\leftarrow \sigma_{DNO=5}(EMPLOYEE)$$

RESULT $\leftarrow \pi_{FNAME, LNAME, SALARY}$ (DEP5_EMPS)

• Rename Operation (cont.)

The rename operator is ρ

The general Rename operation can be expressed by any of the following forms:

- $-\ \rho_{\,S\,(B_1,\,B_2,\,...,\,B_n\,)}$ ($R) \ is a renamed relation <math display="inline">S$ based on R with column names $_{B_1,\,B_1,\,....B_n}$ $_{B_n}$
- $-\rho_{S}(R)$ is a renamed relation S based on R (which does not specify column names).
- $\qquad \qquad \rho_{(B_1,\,B_2,\,...,\,B_n)} \left(\ R \right) \ \text{is a renamed relation with column names } B_1,\,B_1,\,....B_n \text{ which does not specify a new relation name.}$

UNION Operation

The result of this operation, denoted by $R \cup S$, is a relation that includes all tuples that are either in R or in S or in both R and S. Duplicate tuples are eliminated.

Example: To retrieve the social security numbers of all employees who either work in department 5 or directly supervise an employee who works in department 5, we can use the union operation as follows:

DEP5_EMPS $\leftarrow \sigma_{DNO=5}$ (EMPLOYEE)

RESULT1 $\leftarrow \pi_{SSN}(DEP5_EMPS)$

RESULT2(SSN) $\leftarrow \pi_{\text{SUPERSSN}}(\text{DEP5_EMPS})$

RESULT \leftarrow RESULT1 \cup RESULT2

The union operation produces the tuples that are in either RESULT1 or RESULT2 or both. The two operands must be "type compatible".

Type Compatibility

• The operand relations $R_1(A_1, A_2, ..., A_n)$ and $R_2(B_1, B_2, ..., B_n)$ must have the same number of attributes, and the domains of corresponding attributes must be compatible; that is, $dom(A_i)=dom(B_i)$ for i=1, 2, ..., n.

• The resulting relation for $R_1 \cup R_2, R_1 \cap R_2$, or R_1 - R_2 has the same attribute names as the *first* operand relation R1 (by convention).

• UNION Example

INTERSECTION OPERATION

The result of this operation, denoted by $R \cap S$, is a relation that includes all tuples that are in both R and S. The two operands must be "type compatible"

Example: The result of the intersection operation (figure below) includes only those who are both students and instructors.

STUDENT \(\cap\) INSTRUCTOR

• Set Difference (or MINUS) Operation

The result of this operation, denoted by R - S, is a relation that includes all tuples that are in R but not in S. The two operands must be "type compatible".

Example: The figure shows the names of students who are not instructors, and the names of instructors who are not students.

INSTRUCTOR-STUDENT

• Notice that both union and intersection are commutative operations; that is

$$R \cup S = S \cup R$$
, and $R \cap S = S \cap R$

• Both union and intersection can be treated as n-ary operations applicable to any number of relations as both are *associative operations*; that is

$$R \cup (S \cup T) = (R \cup S) \cup T$$
, and $(R \cap S) \cap T = R \cap (S \cap T)$

• The minus operation is *not commutative*; that is, in general

$$R - S \neq S - R$$

• CARTESIAN (or cross product) Operation

- This operation is used to combine tuples from two relations in a combinatorial fashion. In general, the result of $R(A_1, A_2, \ldots, A_n) \times S(B_1, B_2, \ldots, B_m)$ is a relation Q with degree n+m attributes $Q(A_1, A_2, \ldots, A_n, B_1, B_2, \ldots, B_m)$, in that order. The resulting relation Q has one tuple for each combination of tuples—one from R and one from S.
- Hence, if R has n_R tuples (denoted as $|R| = n_R$), and S has n_S tuples, then $|R \times S|$ will have $n_R * n_S$ tuples.
- The two operands do NOT have to be "type compatible"

Example:

```
FEMALE_EMPS \leftarrow \sigma_{SEX='F'} (EMPLOYEE)
EMPNAMES \leftarrow \pi_{FNAME, LNAME, SSN} (FEMALE_EMPS)
```

EMP_DEPENDENTS ← **EMPNAMES** x **DEPENDENT**

Binary Relational Operations

JOIN Operation

- The sequence of cartesian product followed by select is used quite commonly to identify and select related tuples from two relations, a special operation, called **JOIN**. It is denoted by a
- This operation is very important for any relational database with more than a single relation, because it allows us to process relationships among relations.
- The general form of a join operation on two relations $R(A_1, A_2, \ldots, A_n)$ and $S(B_1, B_2, \ldots, B_m)$ is:

$$R\bowtie_{\leq join\ condition>} S$$

where R and S can be any relations that result from general relational algebra expressions.

Example: Suppose that we want to retrieve the name of the manager of each department. To get the manager's name, we need to combine each DEPARTMENT tuple with the EMPLOYEE tuple whose SSN value matches the MGRSSN value in the department tuple. We do this by using the join ⋈ operation.

DEPT_MGR	DNAME	DNUMBER	MGRSSN	 FNAME	MINIT	LNAME	SSN	
	Research	5	333445555	 Franklin	Т	Wong	333445555	
	Administration	4	987654321	 Jennifer	S	Wallace	987654321	
	Headquarters	1	888665555	 James	E	Borg	888665555	

• EQUIJOIN Operation

The most common use of join involves join conditions with equality comparisons only. Such a join, where the only comparison operator used is =, is called an EQUIJOIN. In the result of an EQUIJOIN we always have one or more pairs of attributes (whose names need not be identical) that have *identical values* in every tuple.

The JOIN seen in the previous example was EQUIJOIN.

NATURAL JOIN Operation

Because one of each pair of attributes with identical values is superfluous, a new operation called natural join—denoted by *—was created to get rid of the second (superfluous) attribute in an EQUIJOIN condition.

The standard definition of natural join requires that the two join attributes, or each pair of corresponding join attributes, have the **same name** in both relations. If this is not the case, a renaming operation is applied first.

Example: To apply a natural join on the DNUMBER attributes of DEPARTMENT and DEPT LOCATIONS, it is sufficient to write:

DEPT_LOCS ← **DEPARTMENT** * **DEPT_LOCATIONS**

Complete Set of Relational Operations

• The set of operations including select σ , project π , union \cup , set difference -, and cartesian product X is called a complete set because any other relational algebra expression can be expressed by a combination of these five operations.

• For example:

$$R \cap S = (R \cup S) - ((R - S) \cup (S - R))$$

$$R \qquad \underset{\text{spoin condition}}{\triangleright} S = \qquad \sigma_{\text{spoin condition}} (R \times S)$$

DIVISION Operation

- The division operation is applied to two relations $R(Z) \div S(X)$, where X subset Z. Let Y = Z X (and hence $Z = X \cup Y$); that is, let Y be the set of attributes of R that are not attributes of S.
- The result of DIVISION is a relation T(Y) that includes a tuple t if tuples t_R appear in R with $t_R[Y] = t$, and with $t_R[X] = t_s$ for every tuple t_s in S.
- For a tuple t to appear in the result T of the DIVISION, the values in t must appear in R in combination with *every* tuple in S.

Recap of Relational Algebra Operations

TABLE 6.1 OPERATIONS OF RELATIONAL ALGEBRA

Operation	Purpose	Notation
SELECT	Selects all tuples that satisfy the selection condition from a relation <i>R</i> .	$\sigma_{\text{\tiny }}(R)$
PROJECT	Produces a new relation with only some of the attributes of R, and removes duplicate tuples.	$\pi_{\scriptscriptstyle{\sf }}({\it R})$
THETA JOIN	Produces all combinations of tuples from R_1 and R_2 that satisfy the join condition.	$R_1^{M}_{\text{}} R_2$
EQUIJOIN	Produces all the combinations of tuples from R_1 and R_2 that satisfy a join condition with only equality comparisons.	R_1^{M} <pre></pre>
natural join	Same as EQUIJOIN except that the join attributes of R_2 are not included in the resulting relation; if the join attributes have the same names, they do not have to be specified at all.	$R_1^*_{< \text{JOIN CONDITION}} R_2$, OR $R_1^*_{< \text{JOIN ATTRIBUTES 1>}}$, $C_{< \text{JOIN ATTRIBUTES 2>}} R_2$ OR $R_1^*_{< > } R_2^*$
UNION	Produces a relation that includes all the tuples in R_1 or R_2 or both R_1 and R_2 ; R_1 and R_2 must be union compatible.	$R_1 \cup R_2$
INTERSECTION	Produces a relation that includes all the tuples in both R_1 and R_2 ; R_1 and R_2 must be union compatible.	$R_1 \cap R_2$
DIFFERENCE	Produces a relation that includes all the tuples in R_1 that are not in R_2 ; R_1 and R_2 must be union compatible.	$R_1 - R_2$
CARTESIAN PRODUCT	Produces a relation that has the attributes of R_1 and R_2 and includes as tuples all possible combinations of tuples from R_1 and R_2 .	$R_1 \times R_2$
DIVISION	Produces a relation $R(X)$ that includes all tuples $t[X]$ in $R_1(Z)$ that appear in R_1 in combination with every tuple from $R_2(Y)$, where $Z = X \cup Y$.	$R_1(Z) \div R_2(Y)$

Additional Relational Operations

Aggregate Functions and Grouping

- A type of request that cannot be expressed in the basic relational algebra is to specify mathematical **aggregate functions** on collections of values from the database.
- Examples of such functions include retrieving the average or total salary of all employees or the total number of employee tuples. These functions are used in simple statistical queries that summarize information from the database tuples.
- Common functions applied to collections of numeric values include SUM, AVERAGE, MAXIMUM, and MINIMUM. The COUNT function is used for counting tuples or values.

(a)	R	DNO	NO_OF_EMPLOYEES	AVERAGE_SAL	
		5	4	33250	
		4	3	31000	
		1	1	55000	

(b)	DNO	COUNT_SSN	AVERAGE_SALARY
	5	4	33250
	4	3	31000
	1	1	55000

(c)	COUNT_SSN	AVERAGE_SALARY
	8	35125

Use of the Functional operator ${\mathcal F}$

 $\mathcal{F}_{\text{MAX Salary}}$ (Employee) retrieves the maximum salary value from the Employee relation

 $\mathcal{F}_{ ext{MIN Salary}}$ (Employee) retrieves the minimum Salary value from the Employee relation

 $\mathcal{F}_{\text{SUM Salary}}$ (Employee) retrieves the sum of the Salary from the Employee relation

DNO $\mathcal{F}_{COUNT\,SSN,\,AVERAGE\,Salary}$ (Employee) groups employees by DNO (department number) and computes the count of employees and average salary per department. [Note: count just counts the number of rows, without removing duplicates]

Recursive Closure Operations

- Another type of operation that, in general, cannot be specified in the basic original relational algebra is **recursive closure**. This operation is applied to a **recursive relationship**.
- An example of a recursive operation is to retrieve all SUPERVISEES of an EMPLOYEE e at all levels—that is, all EMPLOYEE e' directly supervised by e; all employees e' directly supervised by each employee e'; all employees e'' directly supervised by each employee e'; and so on .
- Although it is possible to retrieve employees at each level and then take their union, we cannot, in general, specify a query such as "retrieve the supervisees of 'James Borg' at all levels" without utilizing a looping mechanism.
- The SQL3 standard includes syntax for recursive closure.

(Borg's SSN is 888665555)

(SSN) (SUPERSSN)

SUPERVISION	SSN1	SSN2	
	123456789	333445555	
	333445555	888665555	
	999887777	987654321	
	987654321	888665555	
	666884444	333445555	
	453453453	333445555	
	987987987	987654321	

RESULT 1	SSN	
	333445555	
	987654321	

(Supervised by Borg)

RESULT 2	SSN
	123456789
	999887777
	666884444
	453453453
	987987987

(Supervised by Borg's subordinates)

RESULT	SSN	
	123456789	
	999887777	
	666884444	
	453453453	
	987987987	
	333445555	
	987654321	

(RESULT1 ∪ RESULT2)

The OUTER JOIN Operation

- In NATURAL JOIN tuples without a *matching* (or *related*) tuple are eliminated from the join result. Tuples with null in the join attributes are also eliminated. This amounts to loss of information.
- A set of operations, called outer joins, can be used when we want to keep all the tuples in R, or all those in S, or all those in both relations in the result of the join, regardless of whether or not they have matching tuples in the other relation.
- The left outer join operation keeps every tuple in the *first* or *left* relation R in R S; if no matching tuple is found in S, then the attributes of S in the join result are filled or "padded" with null values.
- A similar operation, right outer join, keeps every tuple in the *second* or right relation S in the result of R S.
- A third operation, full outer join, denoted by keeps all tuples in both the left and the right relations when no matching tuples are found, padding them with null values as needed.

RESULT	FNAME	MINIT	LNAME	DNAME
	John	В	Smith	null
	Franklin	Т	Wong	Research
	Alicia	J	Zelaya	null
	Jennifer	S	Wallace	Administration
	Ramesh	K	Narayan	null
	Joyce	Α	English	null
	Ahmad	٧	Jabbar	null
	James	Е	Borg	Headquarters

OUTER UNION Operations

- The outer union operation was developed to take the union of tuples from two relations if the relations are *not union compatible*.
- This operation will take the union of tuples in two relations R(X, Y) and S(X, Z) that are **partially compatible**, meaning that only some of their attributes, say X, are union compatible.
- The attributes that are union compatible are represented only once in the result, and those attributes that are not union compatible from either relation are also kept in the result relation T(X, Y, Z).
- Example: An outer union can be applied to two relations whose schemas are STUDENT(Name, SSN, Department, Advisor) and INSTRUCTOR(Name, SSN, Department, Rank). Tuples from the two relations are matched based on having the same combination of values of the shared attributes—Name, SSN, Department. If a student is also an instructor, both Advisor and Rank will have a value; otherwise, one of these two attributes will be null.

The result relation STUDENT_OR_INSTRUCTOR will have the following attributes:

STUDENT_OR_INSTRUCTOR (Name, SSN, Department, Advisor, Rank)

Examples of Queries in Relational Algebra

• Q1: Retrieve the name and address of all employees who work for the 'Research' department.

```
RESEARCH_DEPT \leftarrow \sigma dname='research' (DEPARTMENT)

RESEARCH_EMPS \leftarrow (RESEARCH_DEPT \bowtie dnumber=
dnoemployeeEMPLOYEE)

RESULT \leftarrow \pi fname, lname, address (RESEARCH_EMPS)
```

• Q6: Retrieve the names of employees who have no dependents.

```
MLL_EMPS \leftarrow \pi \text{ ssn}(\text{EMPLOYEE})

EMPS_WITH_DEPS(SSN) \leftarrow \pi \text{ essn}(\text{DEPENDENT})

EMPS_WITHOUT_DEPS \leftarrow (\text{ALL\_EMPS - EMPS\_WITH\_DEPS})

RESULT \leftarrow \pi \text{ lname}, fname (EMPS_WITHOUT_DEPS * EMPLOYEE)

Module 3.1
```
